## STUDIES RELATED TO CUSMAP

This report presents the results of a geochemical survey of the Reno  $1^{\circ} \times 2^{\circ}$  quadrangle, Nevada and California. Stream-sediment samples initially collected for the National Uranium Resource Evaluation (NURE) Program were reanalyzed in order to provide data for regional (1:250,000) geochemistry as one of several multidisciplinary studies associated with the Conterminous United States Mineral Appraisal Program (CUSMAP).

### INTRODUCTION

#### Purpose of Study

The aim of the Reno CUSMAP project is to evaluate the known as well as potential (undiscovered) mineral resources in the Reno  $1^{\circ} \times 2^{\circ}$  quadrangle, Nevada and California. As part of this appraisal, a geochemical investigation was undertaken based on the reanalysis of stream-sediment samples initially collected as part of the National Uranium Resource Evaluation (NURE) Program. The NURE project was established in 1973 to assess uranium resources and identify favorable areas for detailed uranium exploration throughout the United States. The reanalysis of NURE samples allowed for a determination of certain elements not included in the original NURE investigation. The new determinations are helpful in identifying areas with potential for undiscovered mineral resources within the Reno quadrangle. In addition, the new analysis make it possible to corroborate original NURE data that were compiled and published by E.I. du Pont de Nemours and Co. (Bennett, 1980). This report presents a tabulation of the data generated from the reanalyzed NURE samples.

#### Area Description

The Reno  $1^{\circ} \times 2^{\circ}$  quadrangle encompasses approximately  $7450 \text{ mi}^2$  in west-central Nevada and the extreme eastern portions of Sierra and Lassen Counties, California (fig 1). The greater part of the quadrangle lies within the Basin and Range Physiographic Province marked by isolated mountain ranges separated by intermontane basins. Crystalline rocks and rugged terrain, characteristic features of the Sierra Nevada Physiographic Province, outcrop in the Carson Range near Lake Tahoe in the southwest.

The quadrangle usually experiences temperate summers and cold winters. The mean July temperature is about  $23^{\circ}\text{C}$ , in contrast to the mean January temperature of about  $0^{\circ}\text{C}$  (NOAA, 1977). Snowfall in the winter months produces most of the annual precipitation. Major thoroughfares such as Interstate 80 and U.S. Highway 395 plus a host of hard surface primary and secondary roads afford excellent access to most of the quadrangle. Remote areas can generally be reached via numerous graded and unimproved dirt roads.

#### Geologic Setting

Parts of two geologic provinces are present in the Reno quadrangle: the Sierra Nevada Province and the Basin and Range Province (Wilkins, 1984). Rock exposures associated with the Sierra Nevada Province are limited to the Carson Range, which crops out near the western confines of the study area. These rocks for the most part consist of intensely metamorphosed Mesozoic sedimentary units intruded by plutonic rocks of Cretaceous age. Tertiary

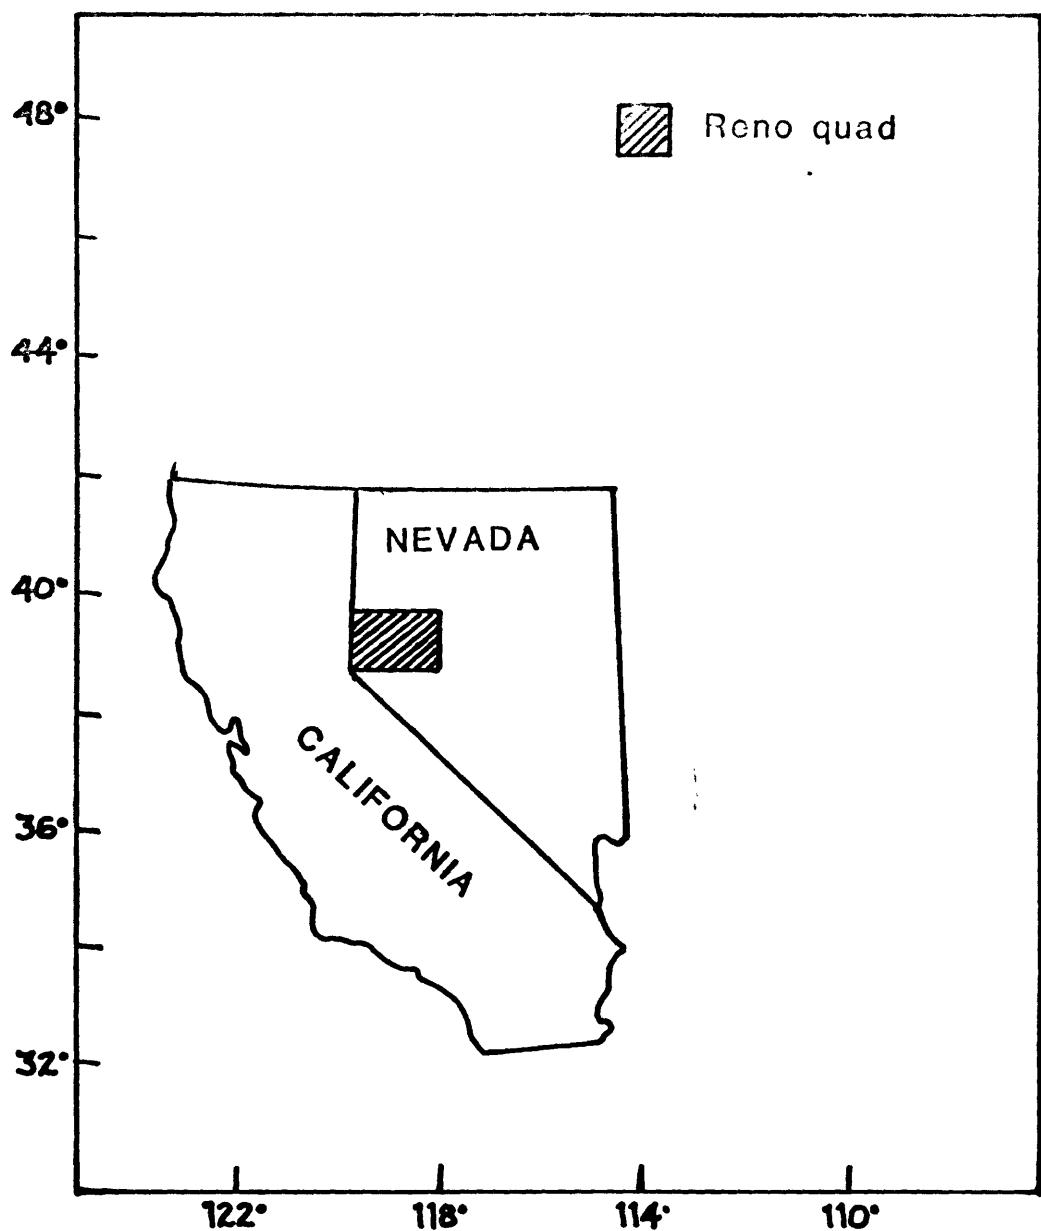

Figure 1. Location of the Reno 1° x 2° quadrangle, Nevada and California.

volcanic and related sedimentary rocks locally overlie the older units. Most of the quadrangle is located in the Basin and Range Province characterized by generally subparallel fault-block mountains separated by broad alluvium filled basins. This sector of the quadrangle is underlain by a sequence of folded and faulted marine sedimentary rocks of Triassic and Jurassic age intruded by a series of Cretaceous granitic plutons. Tertiary volcanic and associated sedimentary rocks blanket much of the area (Stewart, 1980).

### Mining Production and Mineral Deposits

Records of mining activity in the Reno quadrangle indicate a collective yield of more than 14 metals and 10 industrial minerals produced from roughly 48 mining districts. Major deposit types include epithermal gold, tungsten skarn, porphyry copper, volcanogenic uranium, hot spring mercury and gold, and simple stibnite (antimony) deposits. Locations of the major mines and prospects in the Reno quadrangle and information regarding production and deposit type are given in Sidder (1986).

### SAMPLE COLLECTION AND PREPARATION

A total of 960 stream-sediment samples were collected under the direction of the NURE Program during the period March through June 1979. The NURE sampling protocol called for gathering samples from small streams at a nominal density of one site per  $7 \text{ mi}^2$ . The sediment material was dried in an oven at  $\leq 110^\circ \text{ C}$  then sieved and the fraction  $<149 \mu\text{m}$  (-100 mesh) was blended and retained for analysis (Bennett, 1980).

### ANALYTICAL PROCEDURES

#### Spectrographic Method

The stream-sediment samples were analyzed for 31 elements using a semiquantitative, direct-current arc emission spectrographic method (Grimes and Marranzino, 1968). The elements were analyzed and their lower limits of determination are listed in table 1. Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus one reporting interval at the 83 percent confidence level and plus or minus two reporting intervals at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements (iron, magnesium, calcium, and titanium) are given in weight percent; all others are given in parts per million (micrograms/gram).

#### Other Analytical Methods

In addition to emission spectrographic analysis, the samples were also analyzed by colorimetric, atomic absorption, specific ion, and instrumental techniques for 11 elements. These procedures and elements determined are summarized in table 2.

Analytical data for stream-sediment samples from the Reno 1° x 2° quadrangle are found in table 3.

#### ROCK ANALYSIS STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into a computer-based file designated as the Rock Analysis Storage System (RASS). Any or all of this information may be retrieved and converted to a binary form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1977).

#### DESCRIPTION OF DATA TABLE 3

Table 3 lists the results of analysis for the stream-sediment samples. Data are arranged so that column 1 contains the NURE assigned sample numbers. These numbers correspond to the numbers shown on the sample locality map (plate 1). Columns in which the element headings show the letter "s" below the element symbol are emission spectrographic analysis; "aa" indicates atomic absorption analysis; "inst" indicates an instrumental technique; "cm" indicates colorimetric analysis; and "si" indicates specific ion analysis. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination shown for that element in tables 1 or 2. If an element was observed but was below the lowest reporting value, a "less than" symbol (<) was entered in the table in front of the lower limit of determination. If an element was observed but was above the highest reporting value, a "greater than" symbol (>) was entered in the table in front of the upper limit of determination. The dashed symbol "--" in the table indicates no analysis was performed. Because of the formatting used in the computer program that produced table 3, some of the elements listed in the table (Fe, Mg, Ca, Ti, Ag, and Be) carry one or more nonsignificant digits to the right of the significant digits. The analysts did not determine these elements to the accuracy suggested by the extra zeros.
